

0DTE nearest-OTM straddle: per-rule return summary, entry 12:30 ET, held to cash-settle, models compared on the same 866 days

	n	mean	std	min	max	skew	ex. kurt	t	Sharpe _{clk}	n_{buy}	%buy	Sharpe _{clk} ^x
<i>Short volatility (always short)</i>												
all models (no forecast)	866	0.097	0.466	-4.31	0.93	-1.88	10.76	6.12	3.30	0	0.0	2.72
sign(s) (± 1 on the sign of s)												
baseline (HAR + calendar OLS)	866	0.021	0.475	-2.37	4.31	0.59	8.36	1.31	0.71	379	43.8	0.14
block-diagonal ridge	866	0.027	0.475	-2.37	4.31	0.53	8.36	1.69	0.91	369	42.6	0.34
block-diagonal ridge, without the FOMC columns	866	0.024	0.475	-2.37	4.31	0.61	8.35	1.47	0.79	395	45.6	0.22
LightGBM [†]	866	0.024	0.475	-2.37	4.31	0.63	8.34	1.48	0.80	385	44.5	0.23
XGBoost [†]	866	0.024	0.475	-2.37	4.31	0.61	8.35	1.47	0.80	391	45.2	0.22
lasso (causally tuned) [†]	866	0.023	0.475	-2.37	4.31	0.56	8.36	1.44	0.78	406	46.9	0.20
lasso ($\alpha = 10^{-4}$)	866	0.024	0.475	-2.37	4.31	0.53	8.36	1.50	0.81	371	42.8	0.24
elastic net (causally tuned) [†]	866	0.027	0.475	-2.37	4.31	0.54	8.36	1.67	0.90	389	44.9	0.33

block-diagonal ridge, midpoint fills: entry 12:30 ET, held to cash-settle; return of the position, 1st-99th percentile window (bars: the days with $R' \neq 0$)

Distribution of the return of the position taken at 12:30 ET, block-diagonal ridge forecast, one panel per rule (returns inside their 1st–99th percentile window).

One trade a day: enter the nearest-OTM straddle at 12:30 ET, hold those strikes to the official close, and delta-hedge every 30 minutes. 866 expiration days, 2020-01-03 to 2024-04-30 (the deck’s frame). Fills are at the quoted midpoint everywhere except the last column, which is the same rule at the crossed spread: entry at the touch (the ask when long, the bid when short) and cash-settle at the official close (no exit spread). One expiration day = one return; mid fill. Every t here is the plain $t = \sqrt{n} \cdot \text{mean}/\text{std}$, with no autocorrelation correction. “ex. kurt” is the bias-corrected sample excess kurtosis (Gaussian = 0). The short-volatility rule takes no forecast, so it is one row for all models. **Two Sharpes.** Both multiply by $\sqrt{252}$ because an expiration day is the unit of time (same year-length as the paper). They are not the same object. On a *single-clock* page, Sharpe_{clk} = (mean/std) $\times \sqrt{252}$ of that clock’s series: one remaining-session short per expiration day (enter at this clock, hold those strikes to the close, delta-hedge every 30 minutes). It answers “if I only entered at this clock, what is my annual Sharpe?” It is *not* the book’s Sharpe_{ann}. On the *pooled* page, Sharpe_{ann} = (mean/std) $\times \sqrt{252}$ of $R_d^{\text{day}} = \sum_t R'_{d,t}$, the sum of the day’s twelve overlapping remaining-session books. That reserved name is the book’s daily P&L after pooling the session. The twelve books overlap; they are not twelve successive 30-minute holds. Sharpe^x is the same convention at the crossed spread. Every other column is daily. n_{buy} is the number of expiration days with position > 0 (always-short is 0; on the pooled page it is days the sum of the twelve positions is positive); %buy is $100 \cdot n_{\text{buy}}/n$, the notebook’s column. The other column this table adds to the deck’s is Sharpe_{ann}^x, the same rule’s annualized Sharpe at the *crossed spread* instead of the midpoint; every other column is the deck’s.

Forecasts: baseline (HAR + calendar OLS); block-diagonal ridge (HAR block and exogenous block, separate penalties) on the design carrying the FOMC calendar block, and the same ridge on the earlier design without those columns, as a diagnostic row; LightGBM and XGBoost on the all-features design; lasso on the same design, causally tuned vs. fixed $\alpha = 10^{-4}$; elastic net (causally tuned). [†] marks a column still fitted on the earlier design panel; a run of those four on the panel of record is pending. The signal is $s_t = \widehat{RV}_t - IV_{\text{hr}}^2 h_t w_t$: the forecast against the implied variance of the same window. w_t is the expanding mean of each prior day’s remaining-session share of realized variance, $RV_t / \sum_{s \geq t} RV_s$ (in-fit panel history back to 2001), not the ratio of trailing clock-means. On the bars whose vendor implied volatility is a censored solver node the deck’s treatment is used here too — the volatility that reproduces the package midpoint, recovered by bisection over the remaining h_t hours — so every bar carries a signal and no bar sits flat.
